

Turtle conservation

What is turtle conservation?

Turtle conservation is referring to the long terms protection of sea turtles also means developing solution that able to reduce reliance on management requiring direct human involvement.

According to Papua New Guinea consolidated legislation is state that the protection of marine species according to **Fauna (Protection and control) act 1966** (*fisheries management law*) the law state everything should be done and not done.

A brief highlight of the of law

-  Restriction on taking or killing of
-  Turtles sales and purchase of turtles
-  Measuring of turtles
-  Payment for turtles
-  Restriction on taking and killing of other fauna.
-  Prohibition of use of shotguns.

Why should we care about saving the turtles?

Why is turtle conservation important?

Five reasons why turtle conservation is very important.

-  **Turtle help control their prey.** For example, leather -backs help manages amount jelly fish in the ocean. Hawksbill help reefs by eating sponges that compete with them for space
-  **Turtle nesting helps beaches.** The nutrients left behind by eggs and hatching that don't survive provide an important source for coastal vegetation.
-  **Hatching are an important source of food for many animals.** Birds, fish, mammals like raccoons and other rely on plentiful hatchings to survive during nesting seasons
-  **They are important for coastal economics and native communities.** Many place rely on turtle watching or diving for jobs and income and number indigenous communities revere sea turtle as part of their culture.
-  **Green turtle grazing on seagrass is an important way to keep seagrass beds healthy.** Healthy benefits many species and able to store carbon.

What are the different ways of conservation of turtles?

-  Reduce marine debris that may entangle or be accidentally eaten by sea turtles
-  Participate in coastal clean up and reduce plastic use to keep our beach and ocean clean
-  Keeping nesting beaches dark and safe for sea turtles

TURTLE CONSERVATION IN THE COASTAL AREAS

BOB's overarching strategy for marine turtle species management has seven interrelated elements:

1. Monitoring

When we talk about monitoring, we simply mean

-  Identify trends in population distribution and abundance.
-  Identify if changes are outside of the limits of acceptable change.

Example, we should monitor the nesting, courtship, foraging, and migration of turtles.

2. Research

We are to carry out research on other projects underway that are home range and migratory corridors using satellite telemetry, photo identification, genetic stock identification, impacts of climate change, health and diet studies.

-  We have to understand the ecology of marine turtles.
-  We have to understand the causes of changes at the key stages in the species' lifecycles.
-  We have to investigate solutions to mitigate threats.

3. Threat abatement (management) and regulation

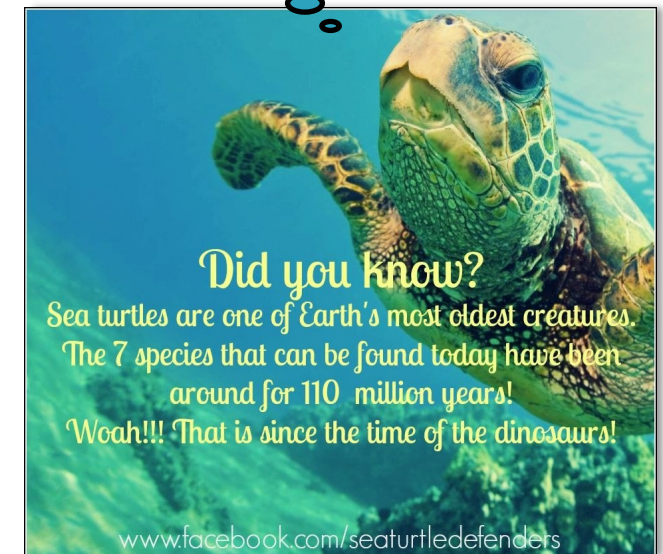

Threats is the main issue faced by sea turtle's human or natural threat. Moreover, the human threat may include pollution that can be monitored by local community or government. In the current event there are project had done throughout Papua New Guinea mainly focus on turtle conservation. An example is in Milne Bay province and at talele island. The program is design in way that is sustainable conservation of turtles

4. Habitat management

Marine turtle populations can benefit from habitat management directed to counter acting the impacts of human activities, including:

-  Removal of weeds and invasive species whose roots negatively impact the incubation success of eggs.
-  Management of shade on nesting beaches to counter the impacts of increasing sand temperatures negatively impacting hatchling sex ratio and hatching success of eggs.

Did you know?

Sea turtles are one of Earth's most oldest creatures.
The 7 species that can be found today have been around for 110 million years!
Woah!!! That is since the time of the dinosaurs!
